What would happen if the probability of a Great Filter causing extinction was much greater than the probability of abiogenesis?

The "Great Filter" is a concept in the study of the origin of life and the possibility of extraterrestrial life that refers to a series of obstacles or "filters" that must be overcome for a civilization to arise and persist. If the probability of a Great Filter causing extinction is much greater than the probability of abiogenesis, this would suggest that the formation of life is a rare and unlikely event, and that the development of intelligent, technologically advanced civilizations is even rarer.

If the Great Filter hypothesis is correct, this would have significant implications for the search for extraterrestrial life and the long-term survival of human civilization. It would suggest that the universe may be largely devoid of life, and that the conditions required for life to emerge and persist are very rare and difficult to achieve.

It's important to note that the Great Filter hypothesis is still a matter of scientific debate, and there is no definitive evidence to support it. While some scientists believe that the Great Filter may pose a significant obstacle to the emergence and persistence of life, others argue that the probability of abiogenesis and the evolution of complex life forms may be higher than previously thought.

As with many scientific questions, the answer to the impact of the Great Filter on the origin of life and the search for extraterrestrial life will likely become clearer as more data and evidence are gathered and analyzed.
